LUNG CANCER DATA ANALYSIS PROJECT

Using Excel & Tableau

By: Debadrita

PROJECT OBJECTIVE

- This project analyzes lung cancer patient data to identify demographic and behavioral risk factors associated with lung cancer cases.

DATASET OVERVIEW

- Dataset Source: Kaggle
- Total Records: 2,998
- Tools Used:
- Excel
- Tableau

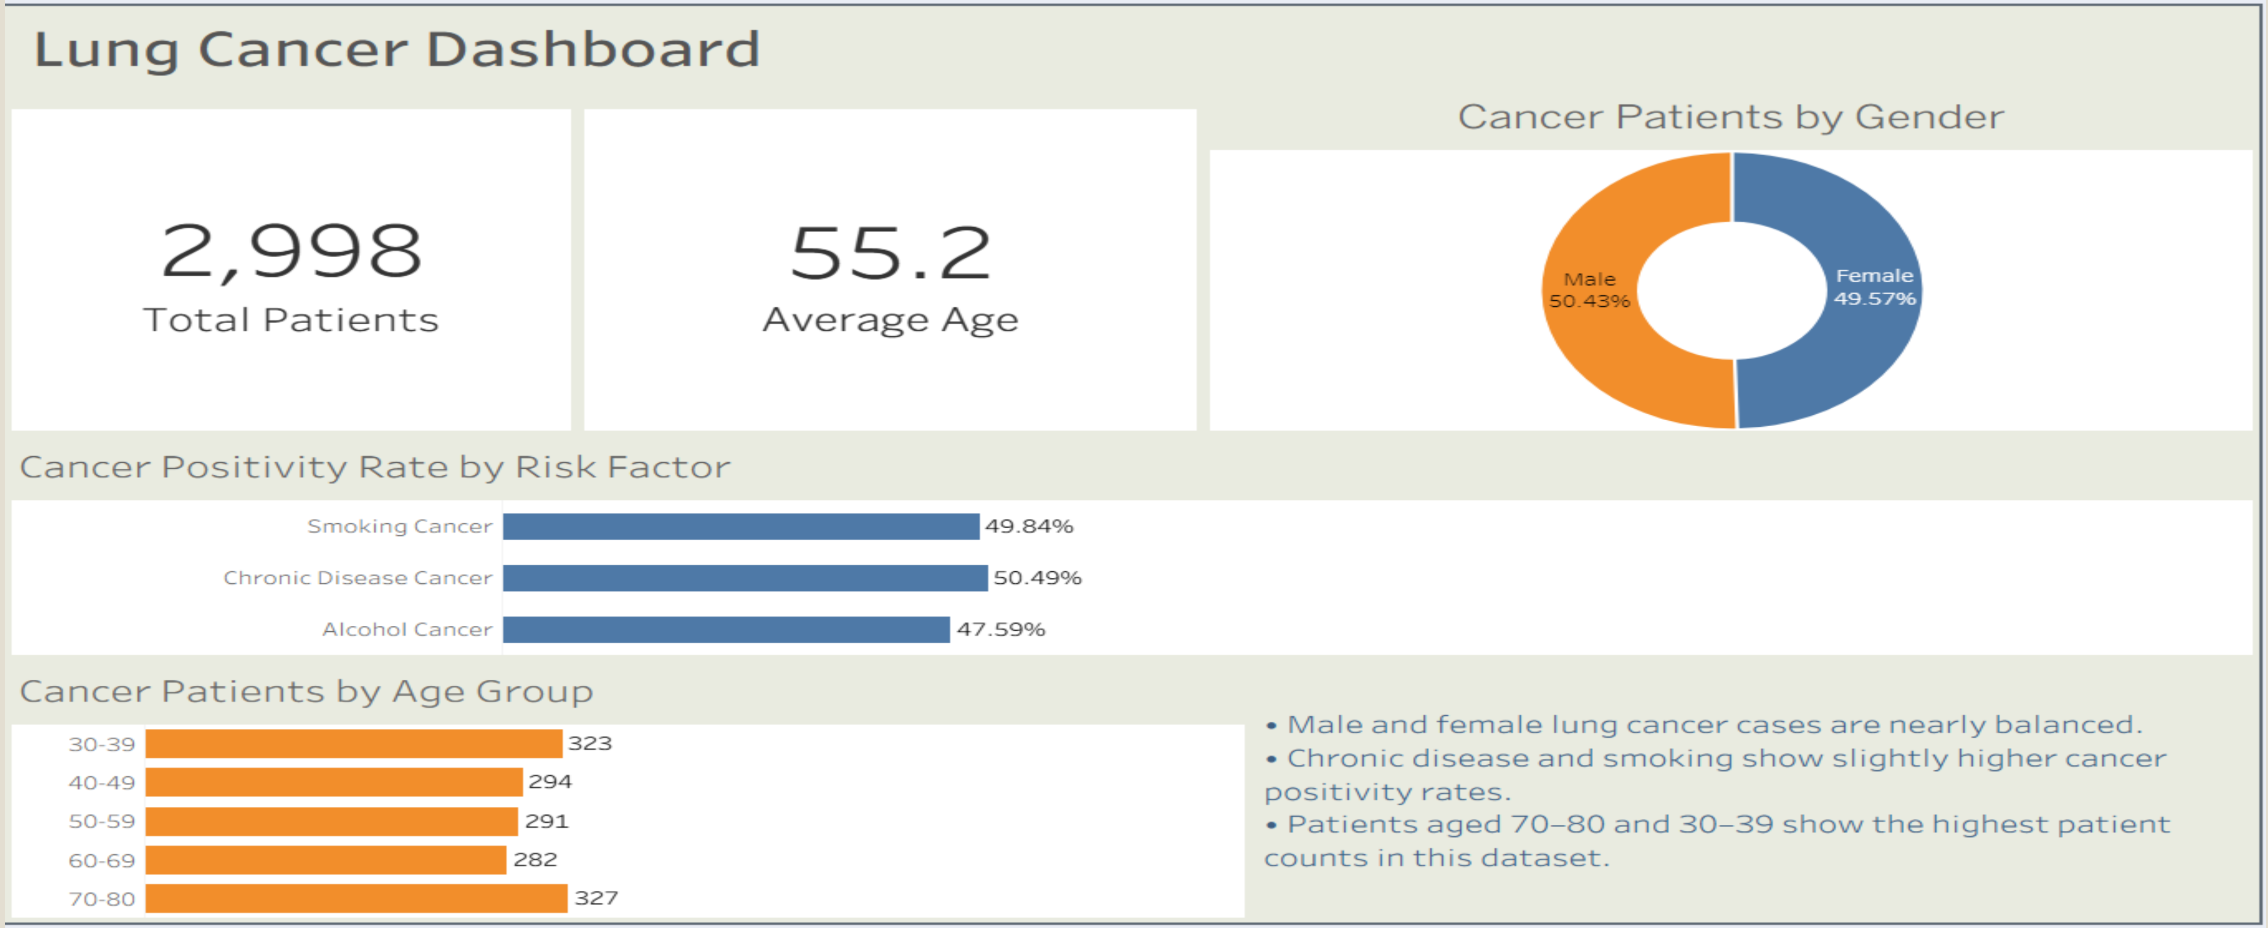
TABLEAU DASHBOARD



The dashboard summarizes patient distribution, age analysis, gender comparison, and cancer positivity rates by major risk factors.

KEY INSIGHTS

- Male and female lung cancer patient distribution is nearly balanced across the dataset.
- Smoking and chronic disease factors show slightly higher cancer positivity rates compared to alcohol consumption.
- Patients aged 30–39 and 70–80 represent comparatively higher patient counts in the dataset
- Chronic disease showed the highest proportion of lung cancer cases within the younger (30–39) age group compared to other factors such as smoking.
- Smoking-associated lung cancer cases were also relatively higher in the 30–39 age category.
- Anxiety showed the highest gender-based variation among observed symptoms, while chest pain showed the least variation.
- Overall symptom distribution appears relatively balanced between genders.

CONCLUSION

- This project helped develop practical skills in data cleaning, exploratory data analysis, dashboard development, and insight communication using Excel and Tableau.
